What is Artificial Intelligence?

Artificial intelligence, or AI, is the ability of a computer program to do tasks that normally need human thinking. Examples include understanding language, recognizing images, and answering questions.

What is a Large Language Model?

A large language model, or LLM, is an AI system trained on huge amounts of text. It learns patterns in language, so it can write, summarize, and answer questions. ChatGPT and Claude are examples of tools built on LLMs.

The Problem With LLMs

An LLM only knows what it saw during training. It has not read your private documents. If you ask about them, it may guess, and sometimes the guess is wrong.

What is RAG?

RAG stands for Retrieval-Augmented Generation. First, the system searches your documents and finds the most relevant parts. Then it gives those parts to the LLM together with your question. The LLM answers using the text it was given, so the answer is based on real information.

Why RAG Matters

RAG makes answers more accurate and lets companies use AI with their own data, such as manuals, policies, and reports, without retraining the model.
